Operating Systems Structure and Processes

Otto J. Anshus
University of Tromsø/Oslo

The Architecture of an OS

- Monolithic
- Layered
- Virtual Machine, Library, Exokernel
- Micro kernel and Client/Server
- Hybrids

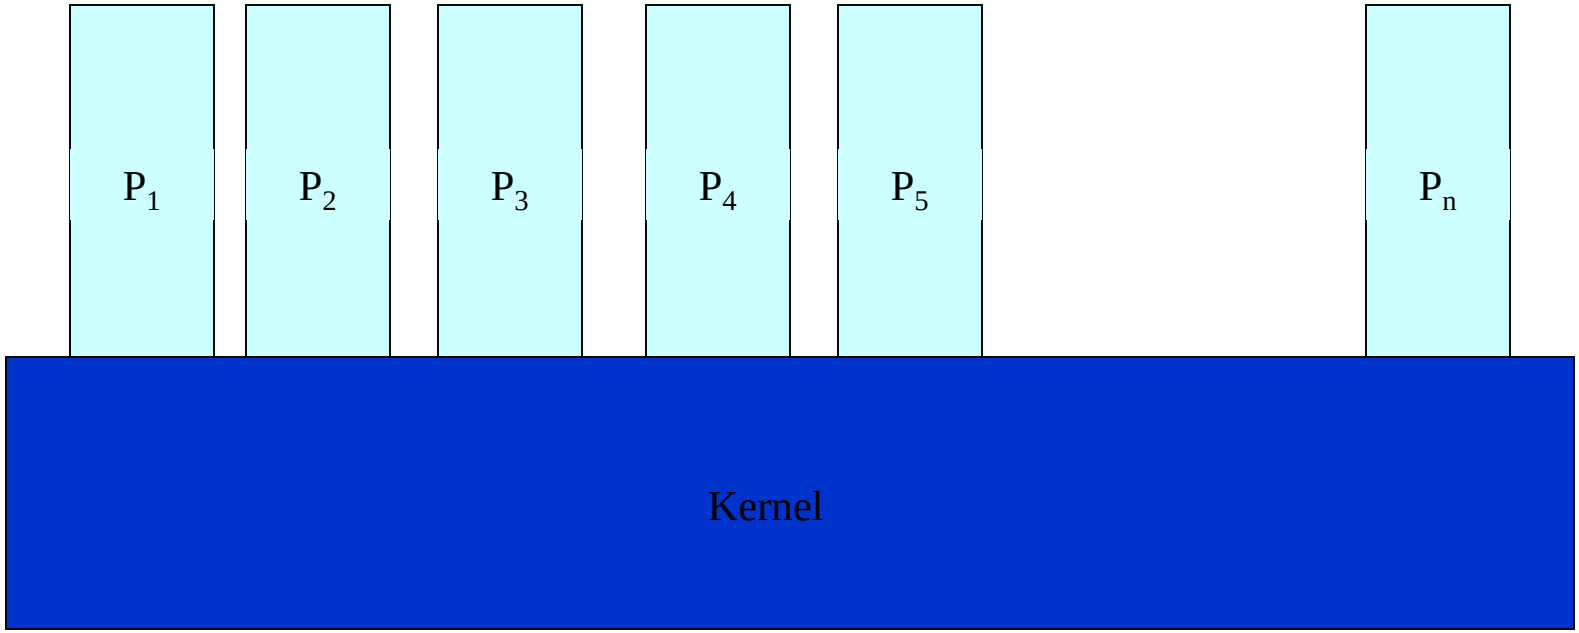
Goals of the architecture

- OS as Resource Manager
- OS as Virtual Machine (abstractions)
- Efficiency, flexibility, size, security, … as discussed earlier

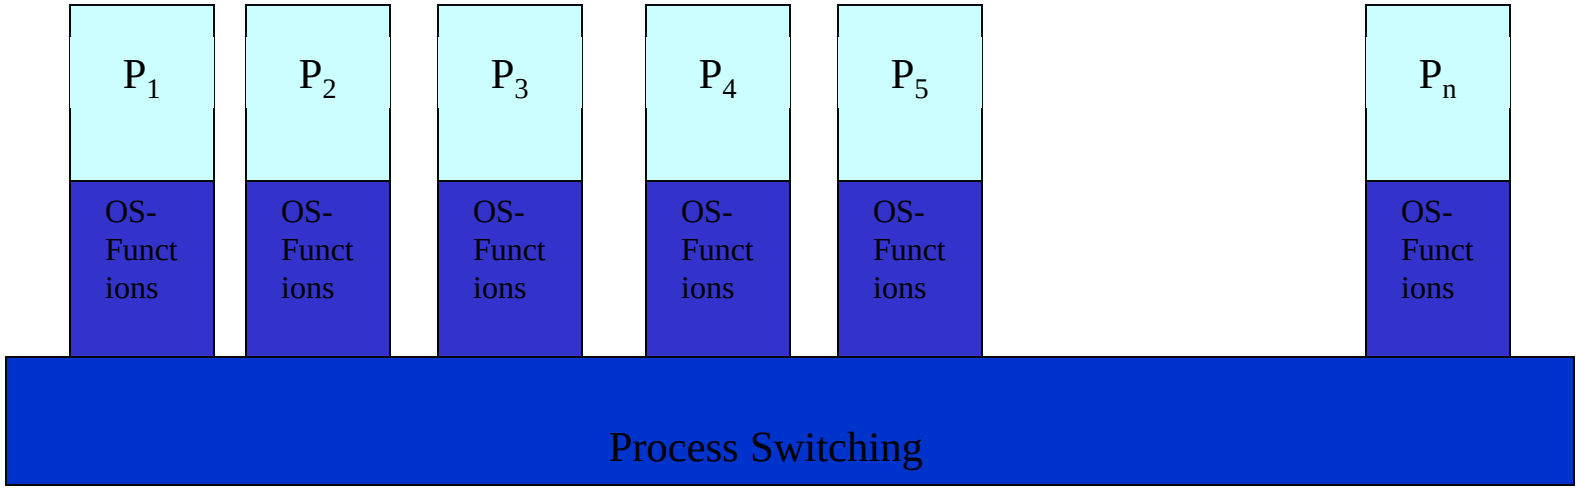
Operating System Use of Processes:
Where is the OS executing?

Illustrations: Stallings

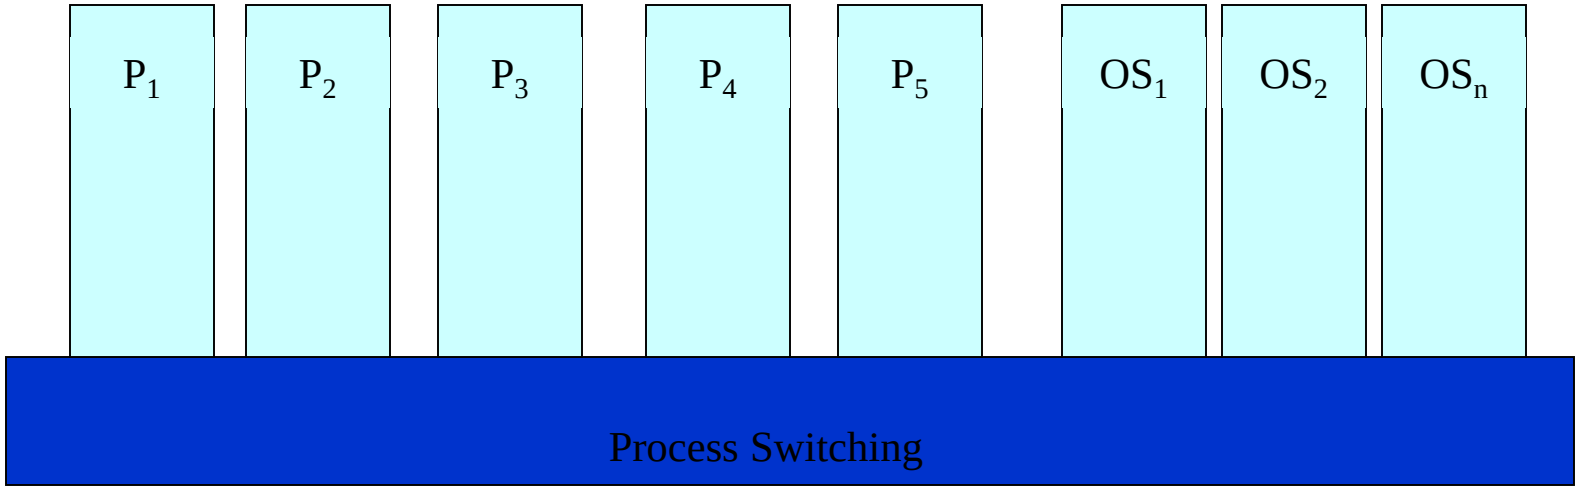
Separate Kernel

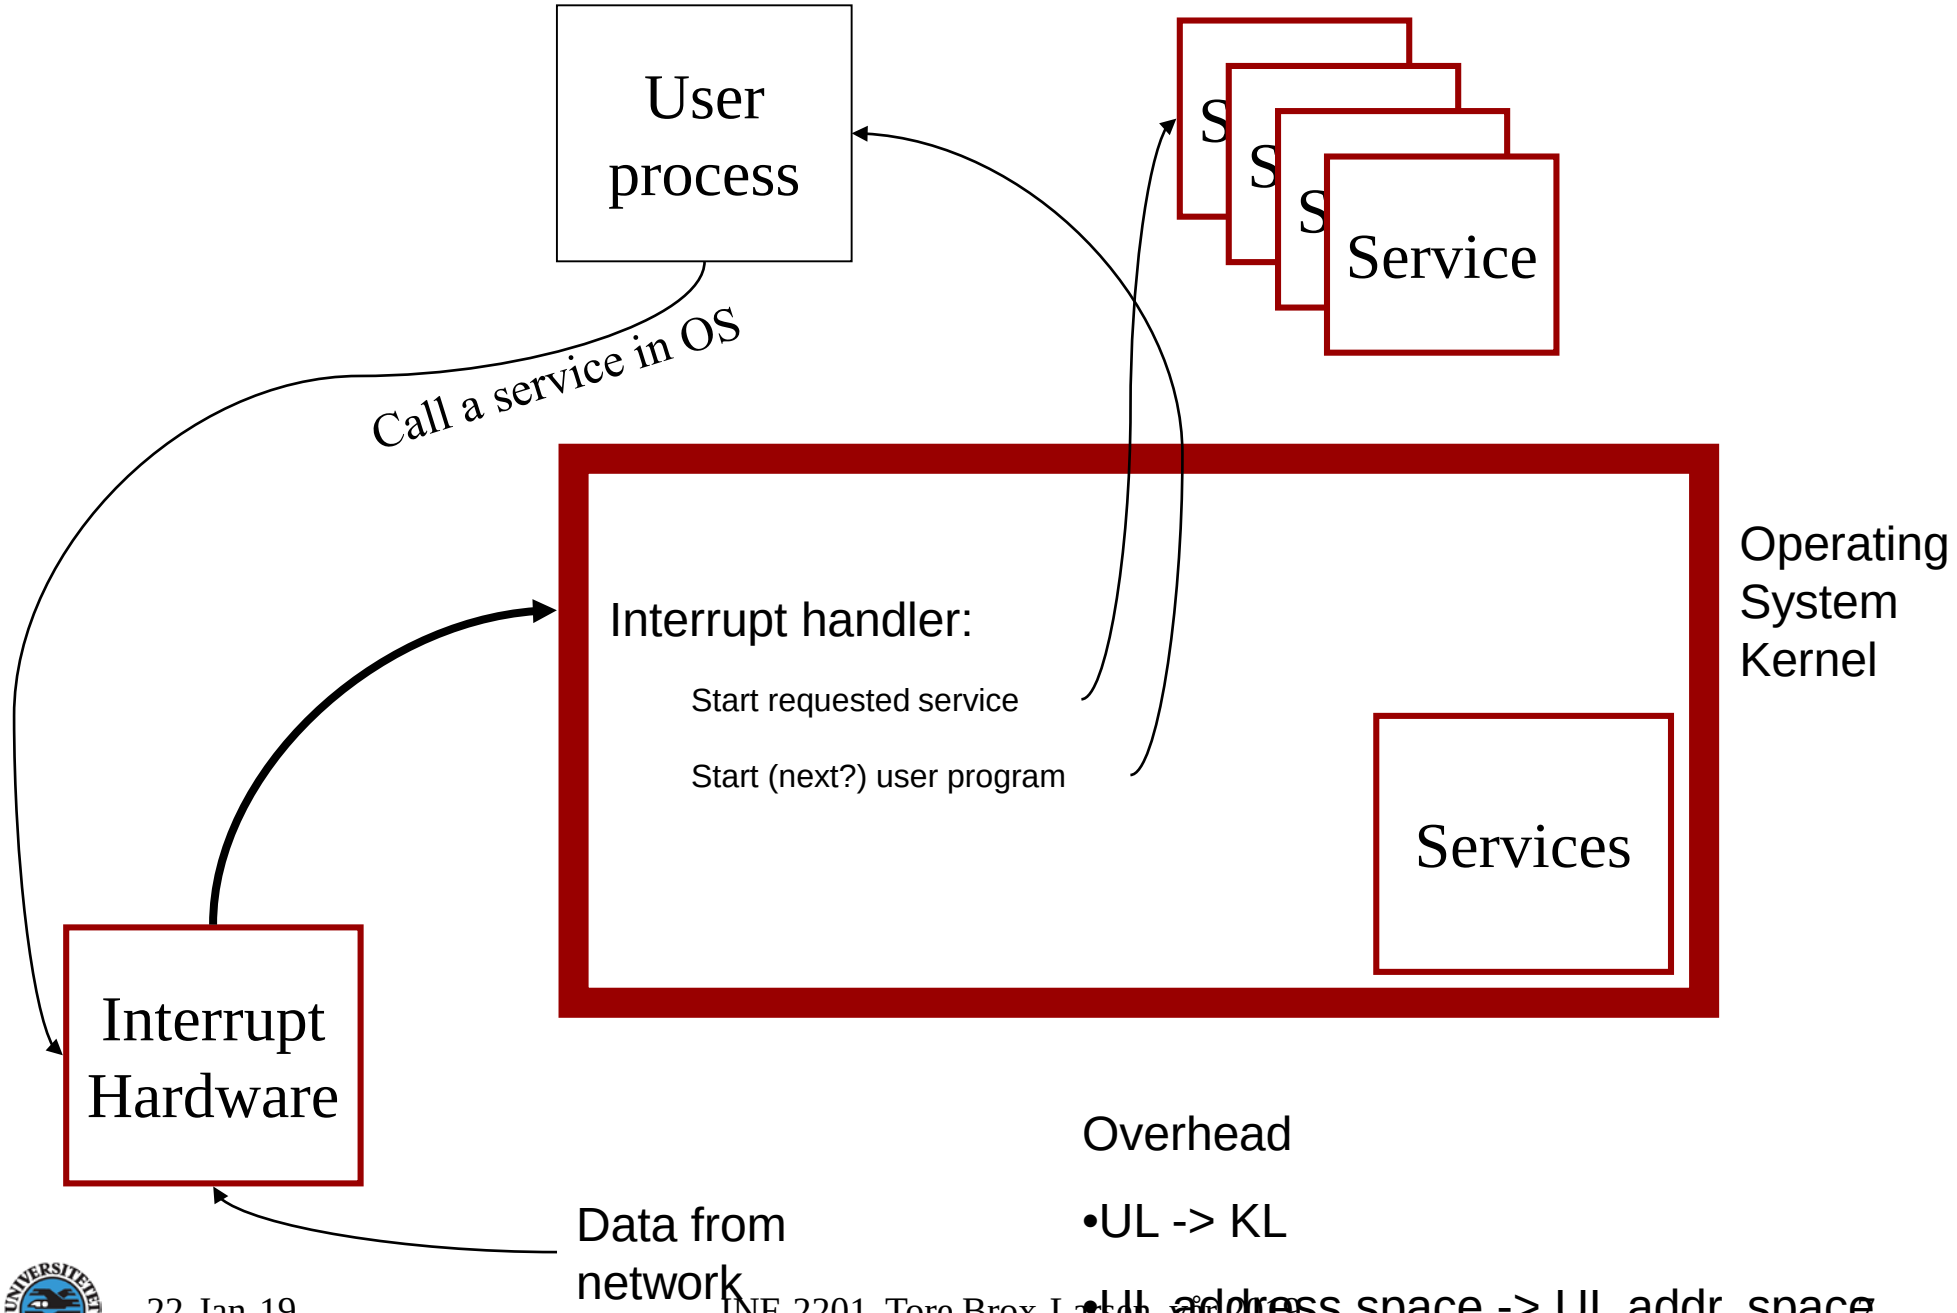


OS-Functions Executing within Processes



OS-Functions Executing in Separate Processes



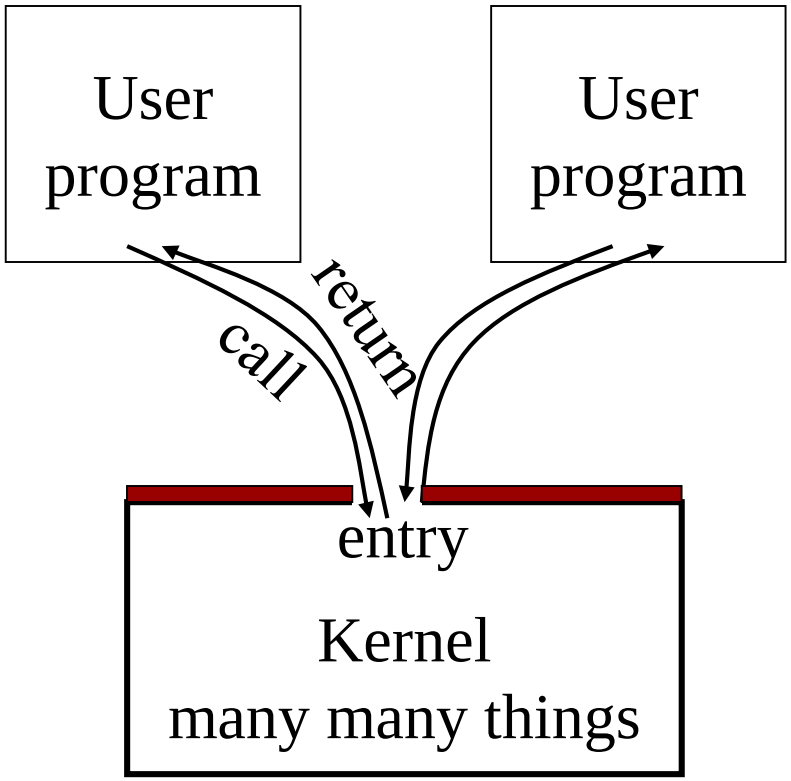


Overhead

- UL -> KL
- UL address space -> UL addr. space

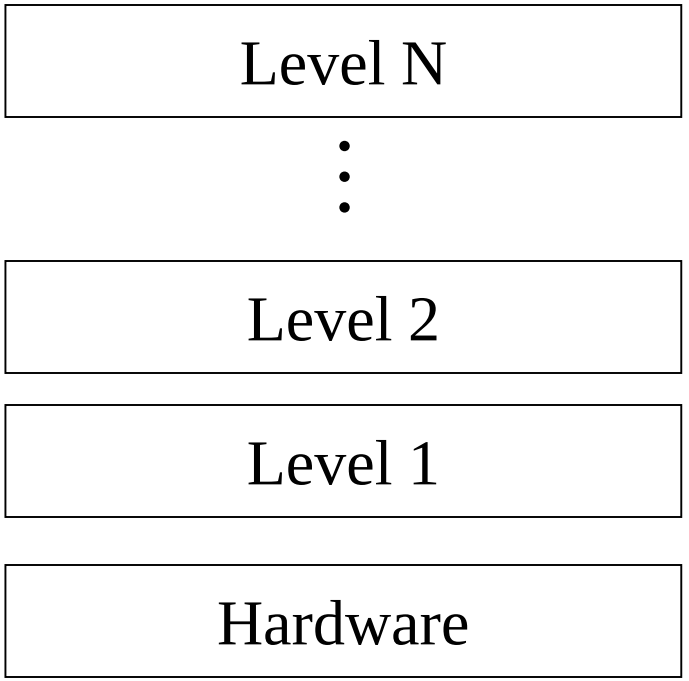
Monolithic

- All kernel routines are together
- A system call interface
- Examples:
  - Linux
  - Most Unix OS
  - NT (hybrid)



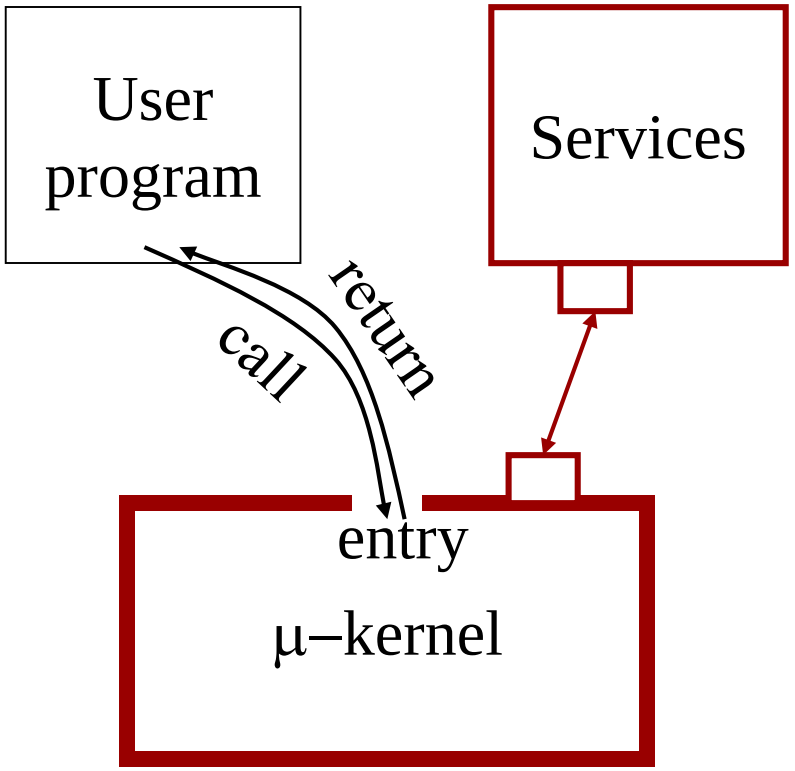
Layered Structure

- Hiding information at each layer
- Develop a layer at a time
- Examples
  - THE (6 layers, semaphores, Dijkstra 1968)
  - MS-DOS (4 layers)



Microkernel and Client/Server

- Micro-kernel is “micro”
- Services are implemented as user level processes
- Micro-kernel get services on behalf of users by messaging with the service processes
- Example: L4, Nucleus, Taos, Mach, Mach, NT (hybrid)



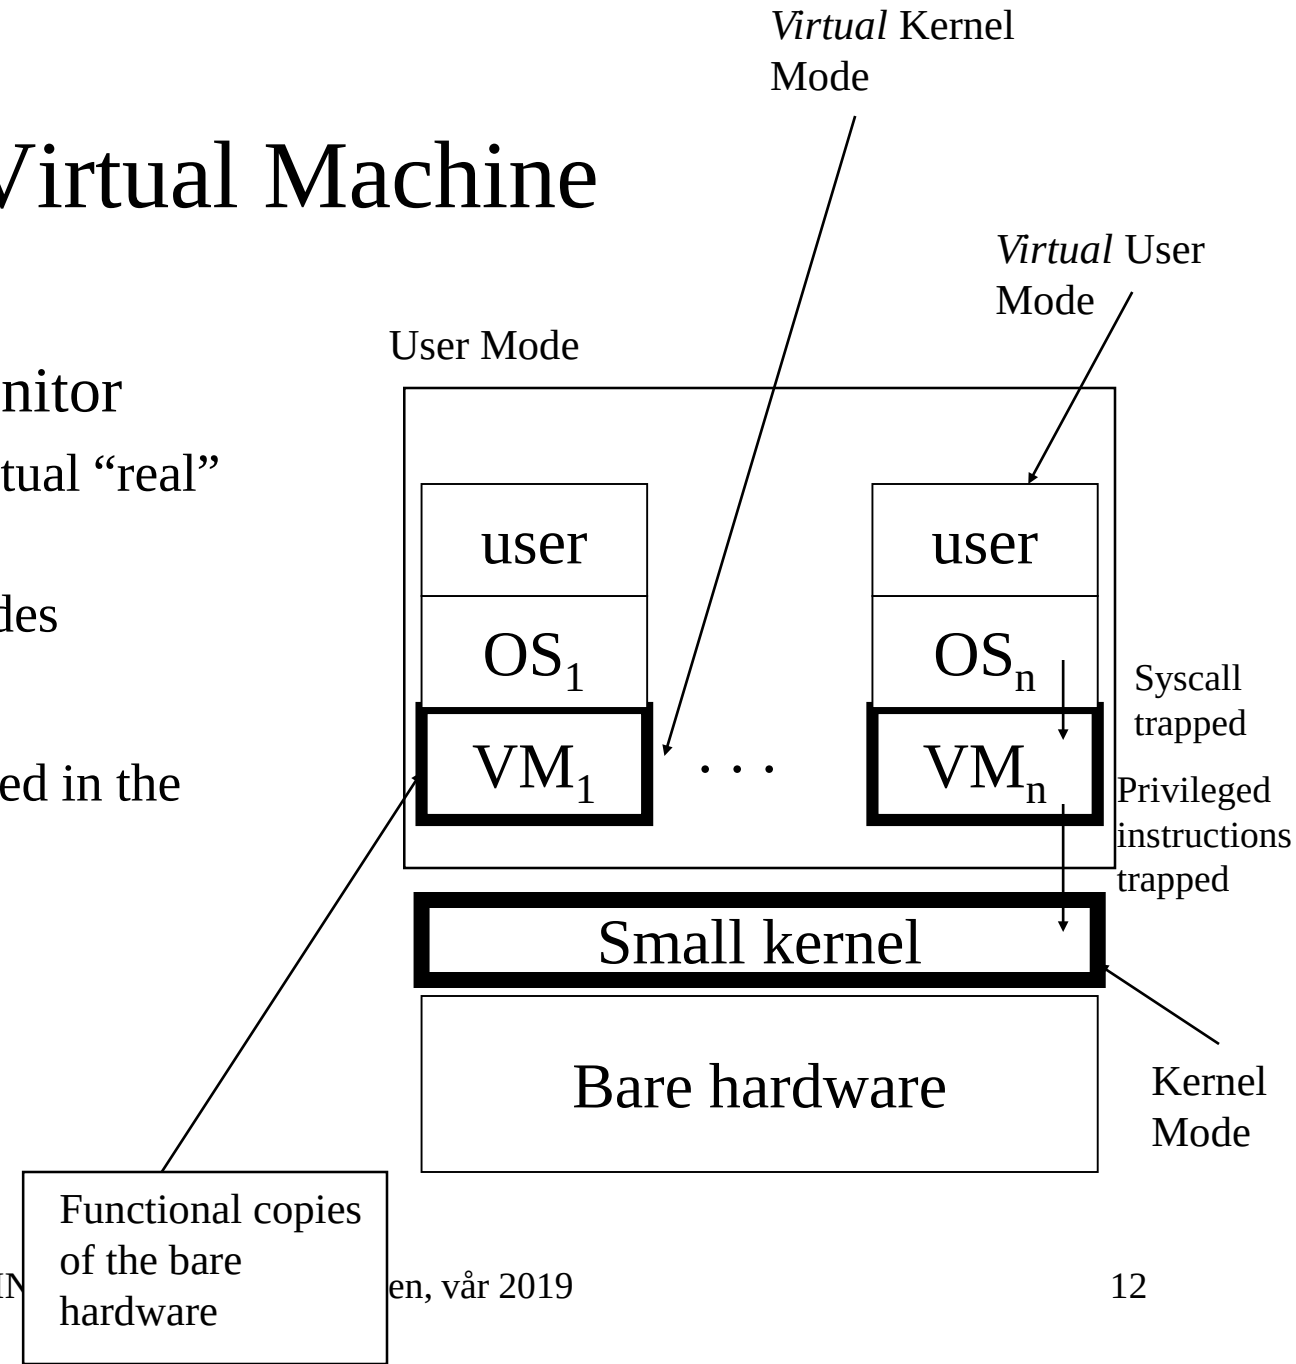
Virtual Machine

"A running program is often referred to as a virtual machine - a machine that doesn't exist as a matter of actual physical reality. The virtual machine idea is itself one of the most elegant in the history of technology and is a crucial step in the evolution of ideas about software. To come up with it, scientists and technologists had to recognize that a computer running a program isn't merely a washer doing laundry. A washer is a washer whatever clothes you put inside, but when you put a new program in a computer, it becomes a new machine.... The virtual machine: A way of understanding software that frees us to think of software design as machine design."

From David Gelernter's "Truth, Beauty, and the Virtual Machine," Discover Magazine, September 1997, p. 72.

Virtual Machine

- Virtual machine monitor
  - provide multiple virtual “real” hardware
  - run different OS codes
- Example
  - IBM VM/370: Started in the 70’s. Check out
  - virtual 8086 mode
  - Java VM
  - VMware
  - Exokernel



Input/Output
Console

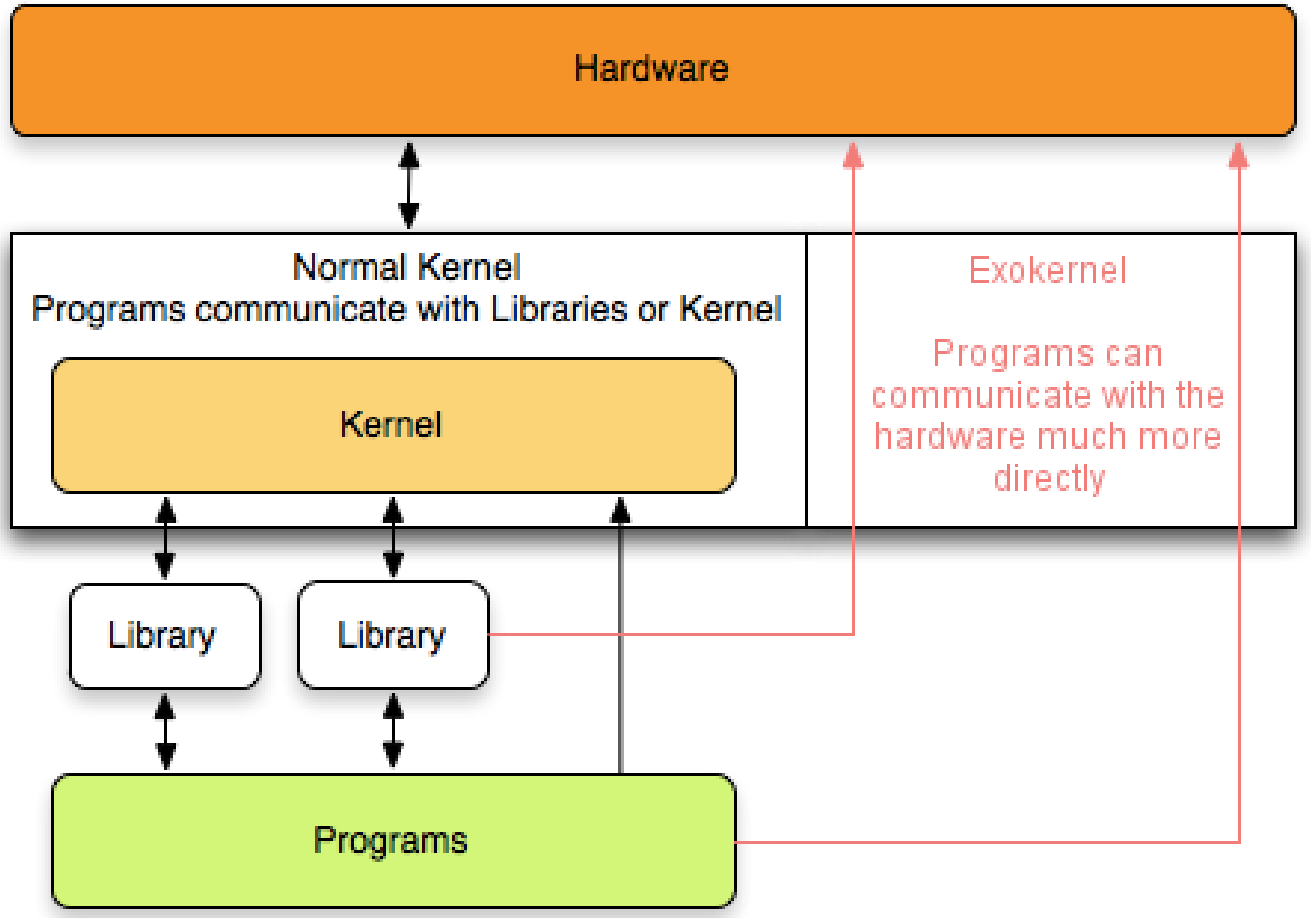
Exokernel Architecture



Hardware Support

- What is the minimal support?
  - 2 modes
  - Exception and interrupt trapping
- Can virtual machine be protected without such support?
  - Yes, emulation instead of executing on real machine

Pro et Contra

Monolithic	Layered	VM	C/S	Micro kernel
•Performance	•Clean, less bugs •Clear division of labour	•Many virtual computers with different OS'es •Test of new OS while production work continues •All in all: flexibility	•Clear division of labour	•More flexible •Small means less bugs+manageable •Distributed systems •Failure isolation of services at Kernel Level
•Less structured	•Are layers really sepaparated? •Performance issues?	•Performance issues? •Complexity issues?	•Performance issues?	•Flexibility issues? •Performance issues?

“Truths” on Micro Kernel Flexibility and Performance

- A micro kernel restricts application level flexibility.
- Switching overhead kernel-user mode is inherently expensive.
- Switching address-spaces is costly.
- IPC is expensive.
- Micro kernel architectures lead to memory
- Kernel should be portable (on top of a small hardware-dependent layer).

NO: Can be <50 cycles

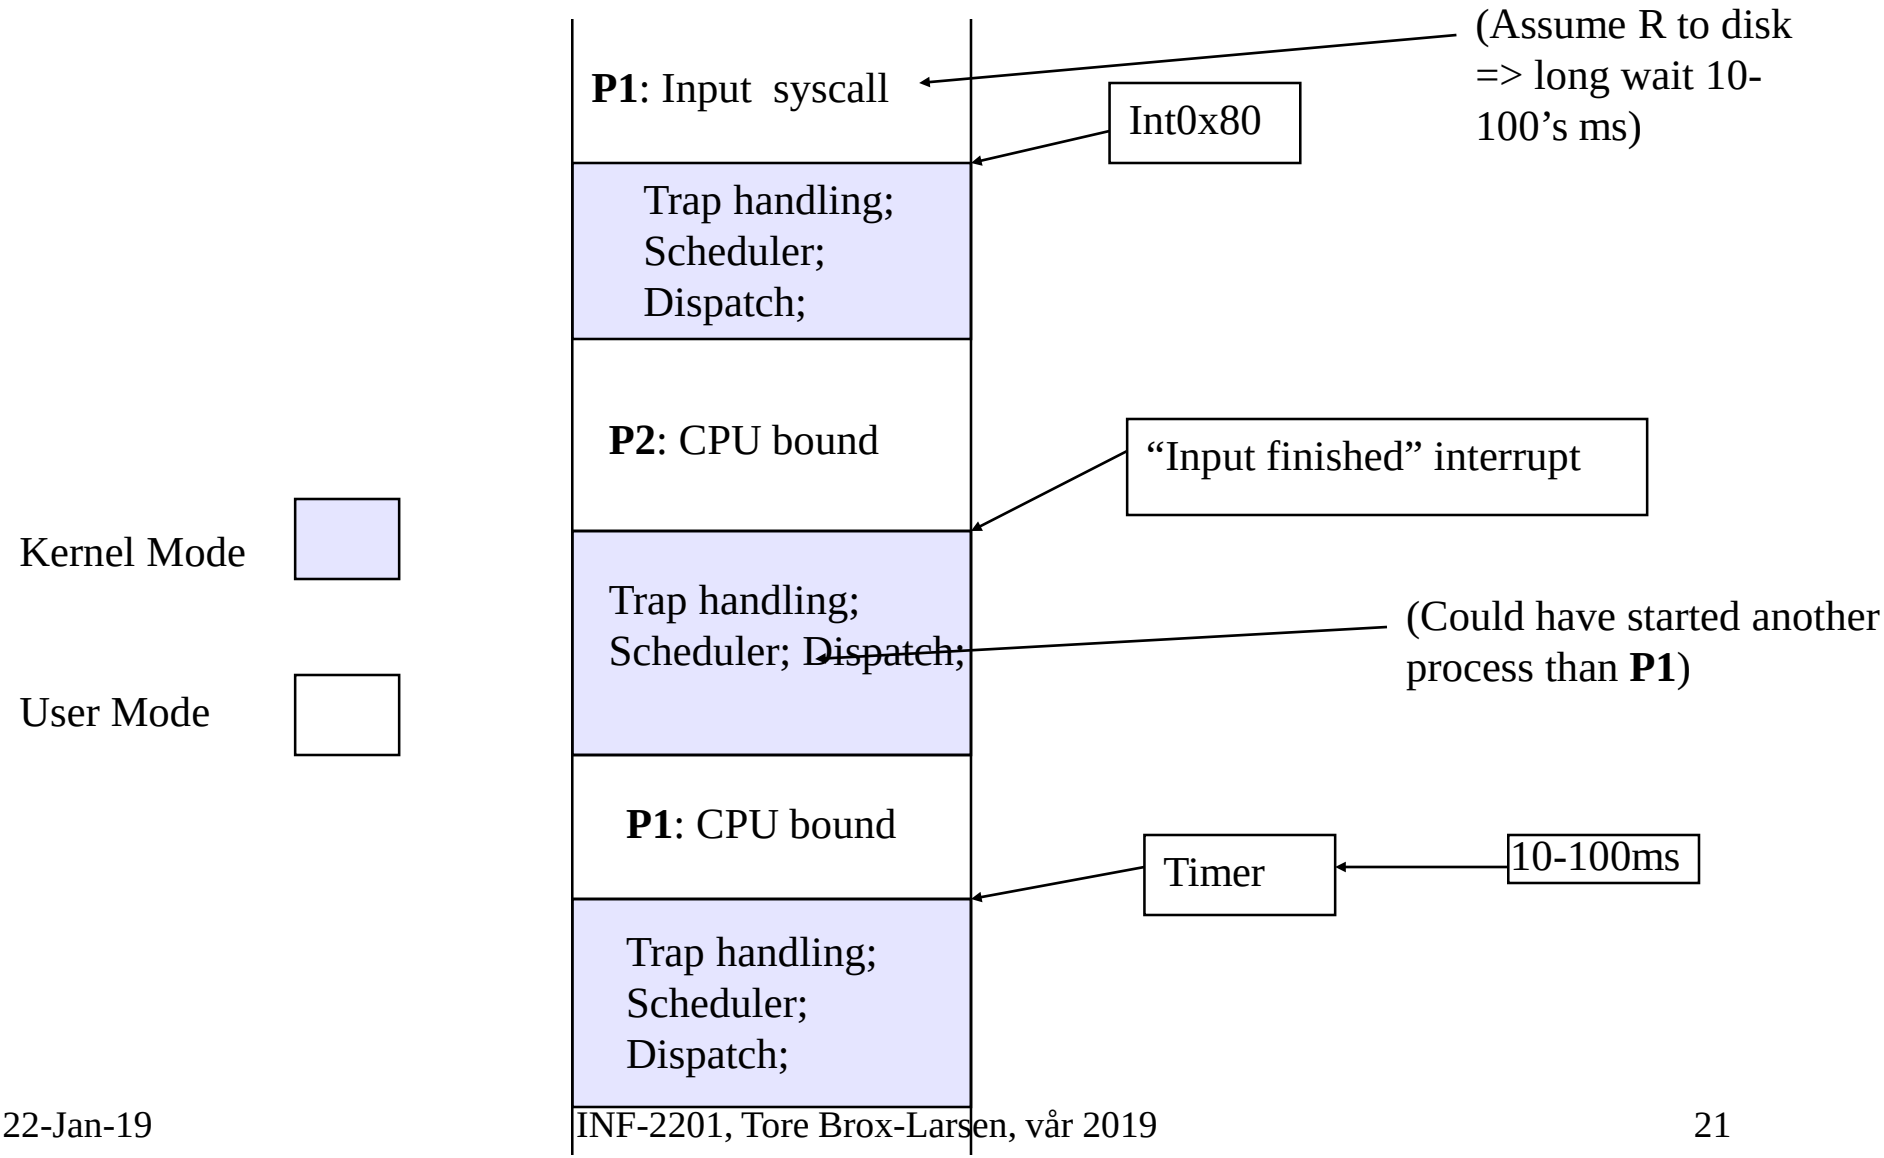
NO: 6-20 microsec round-trip, 53-500 cycles/IPC one way

Taken from Jochen Liedtke, SOSP 15 paper: ”On micro kernel construction”

Concurrency and Process

- Problem to solve
  - A shared CPU, many I/O devices and lots of interrupts
  - Users feel they have machine to themselves
- Strategy
  - Decompose hard problems into simple ones
  - Deal with one at a time
  - Process is such a unit

Flow of Execution

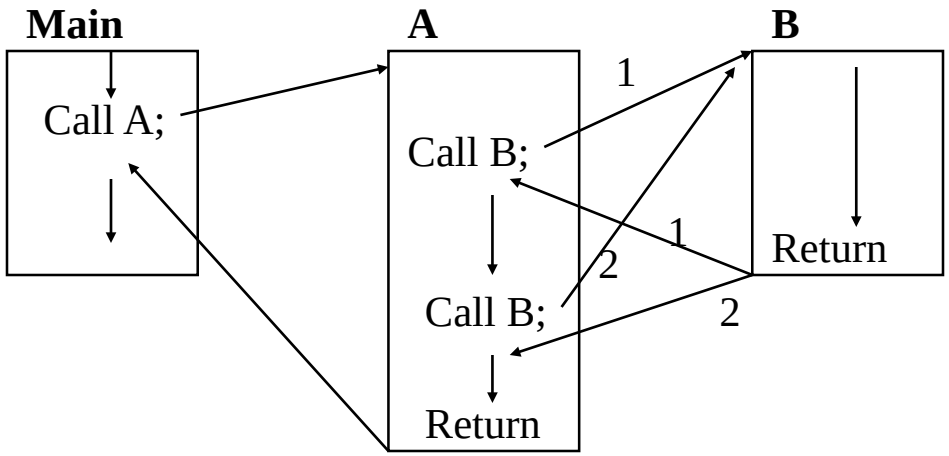


Procedure, Co-routine, Thread, Process

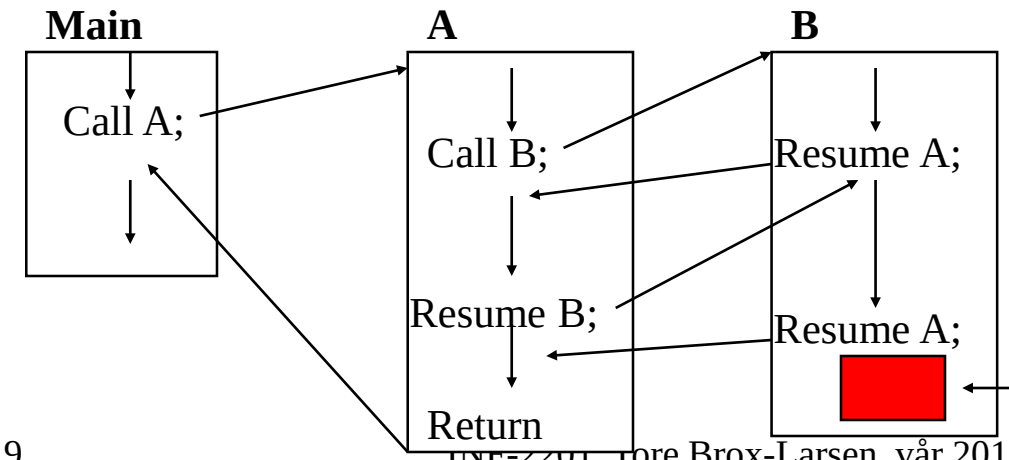
- Procedure, Function, (Sub)Routine
  - Call-execute all-return nesting
- Co-routine
  - Call-resumes-return
- Thread (more later)
- Process
  - Single threaded ↓
  - Multi threaded ↓ ↓ ↓

User level non preemptive “scheduler” in user code

Procedure and Co-routine



"User Yield when finished"



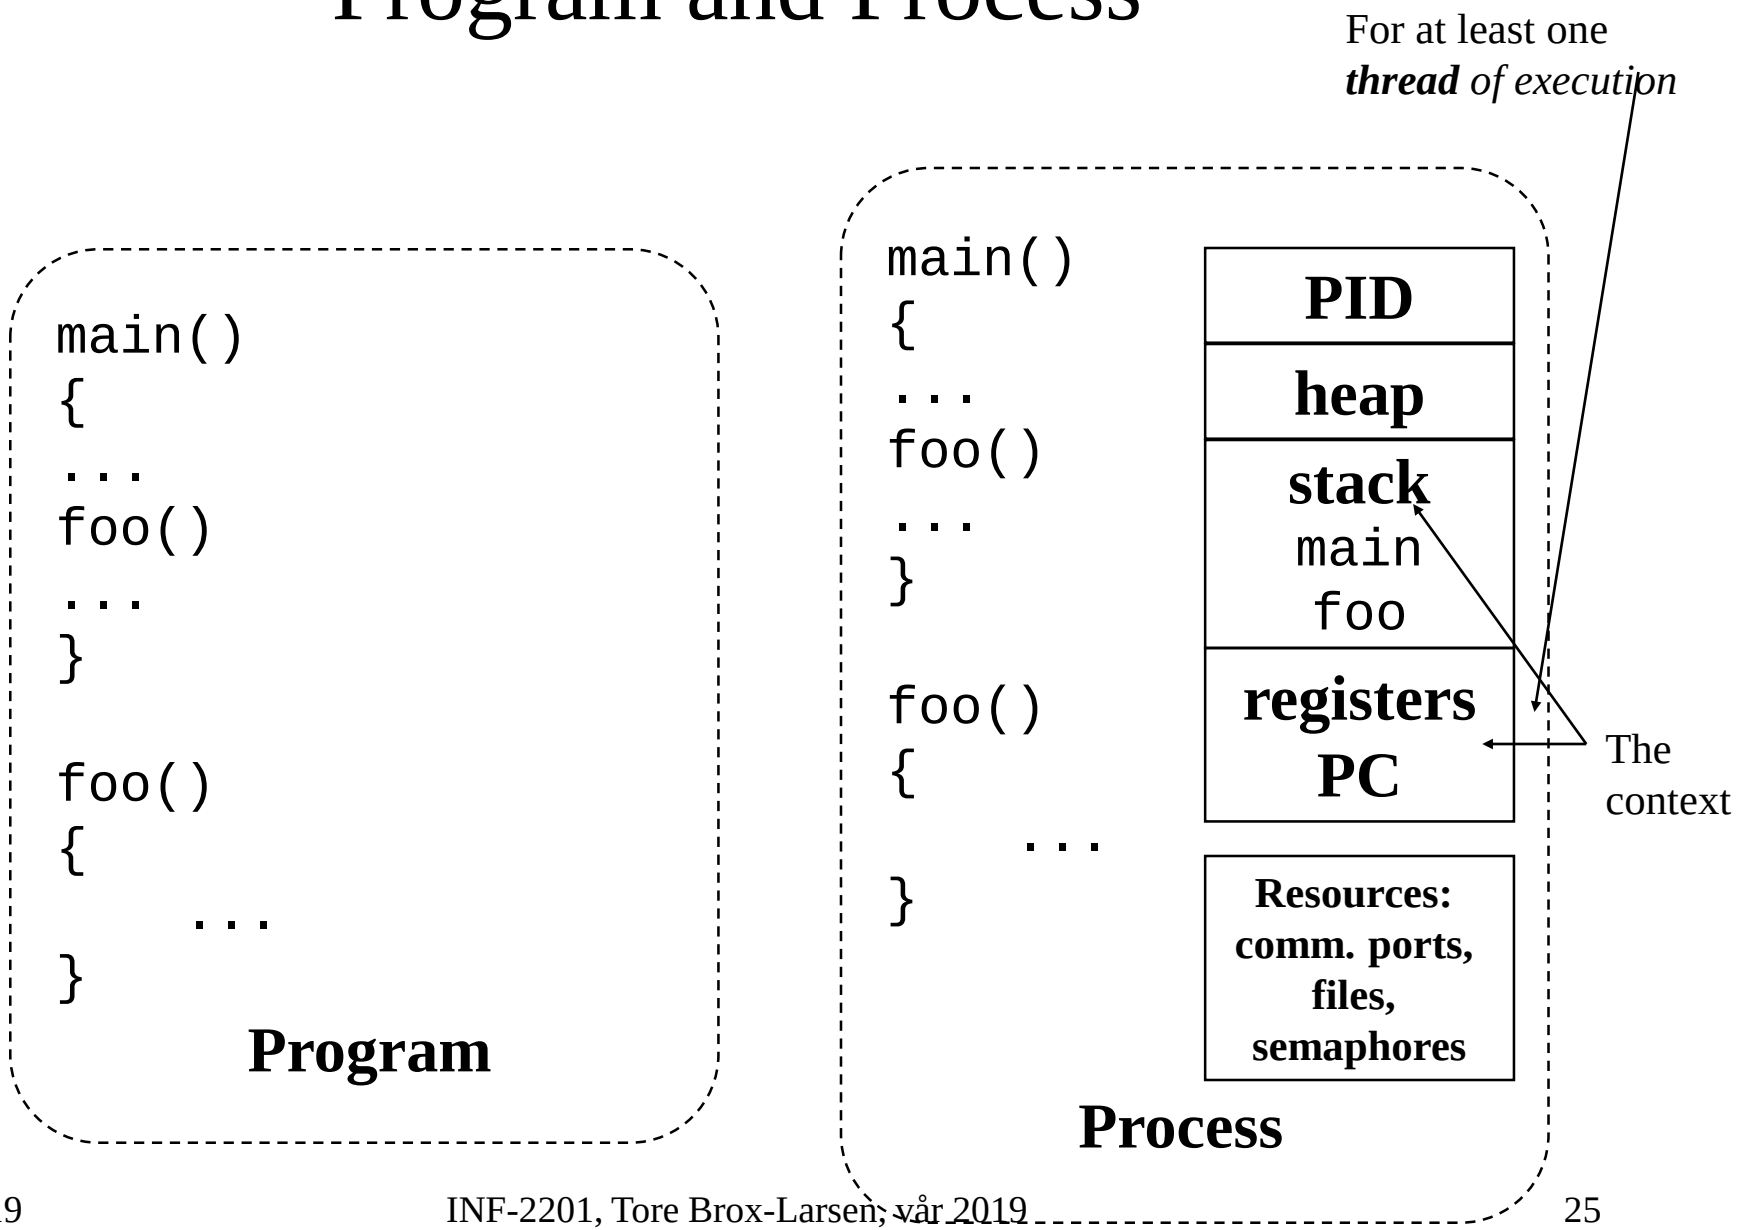
"User Yield during execution to share CPU"

Never executed

Process

- Sequential execution of operations
  - No concurrency inside a (**single** threaded) process
  - Everything happens sequentially
- Process state
  - Registers
  - Stack(s)
  - Main memory
  - Open files in UNIX
  - Communication ports
  - Other resources

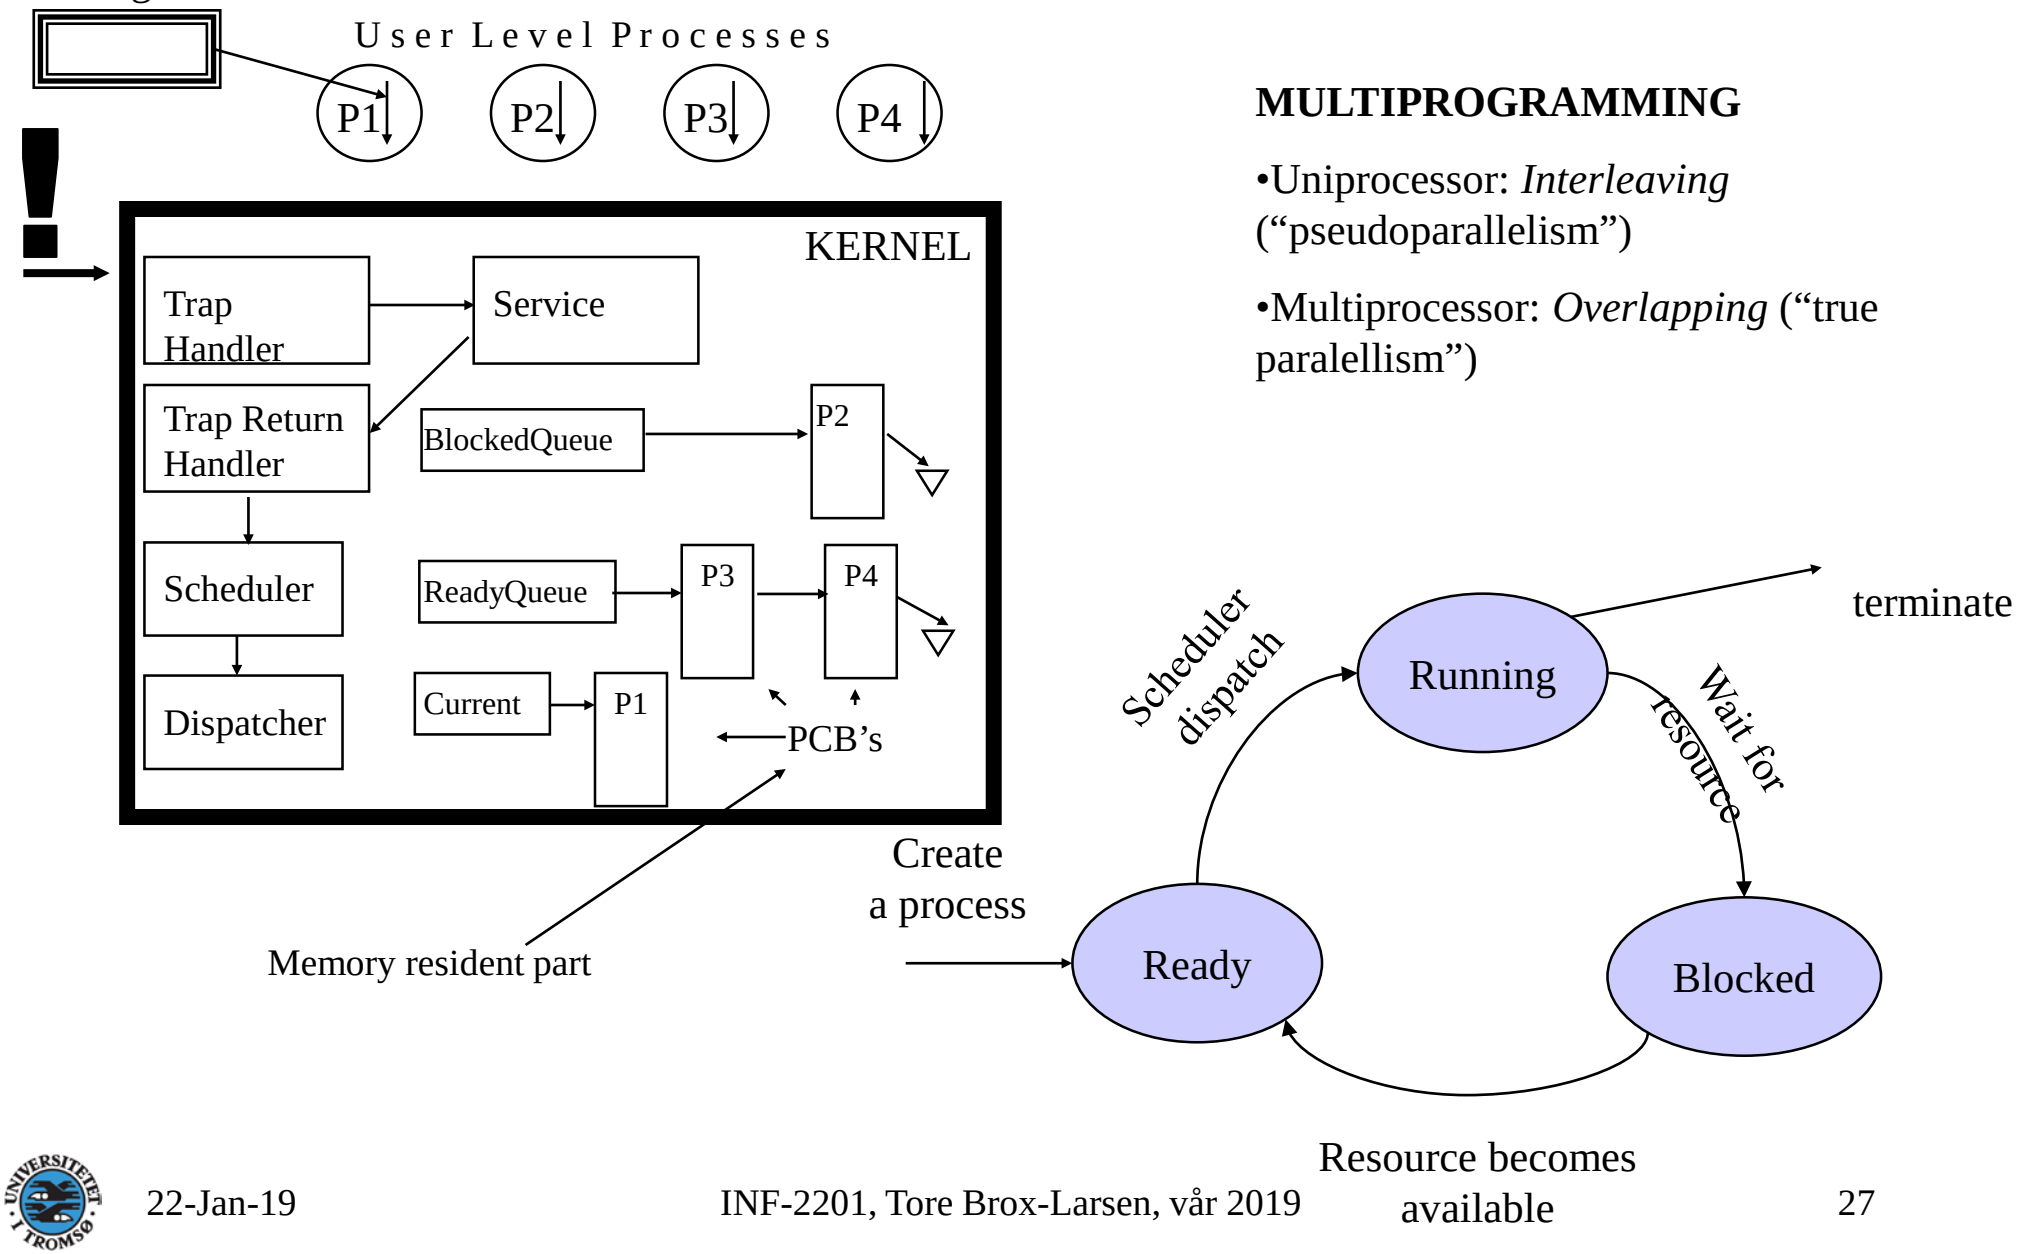
Program and Process



Process vs. Program

- Process > program
  - Program is just part of process state
  - Example: many users can run the same program
- Process < program
  - A program can invoke more than one process
  - Example: Fork off processes to lookup webster

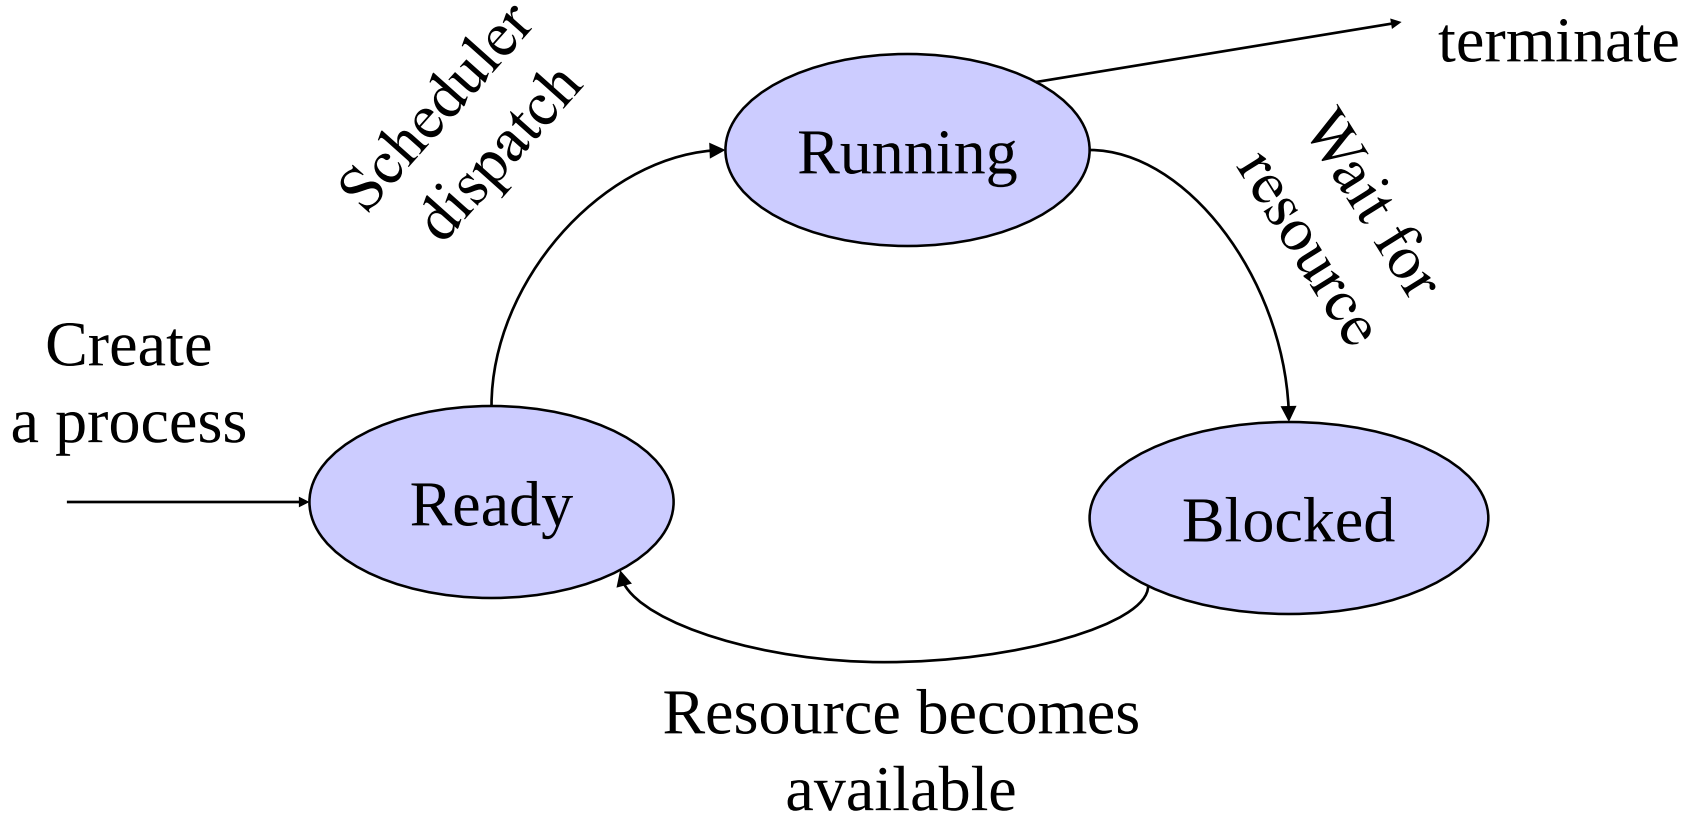
Process State Transitions



MULTIPROGRAMMING

- Uniprocessor: *Interleaving* ("pseudoparallelism")
- Multiprocessor: *Overlapping* ("true paralellism")

Process State Transition



Process Control Block (Process Table)

- What
  - Process management info
    - State (ready, running, blocked)
    - Registers, PSW, parents, etc
  - Memory management info
    - Segments, page table, stats, etc
  - I/O and file management
    - Communication ports, directories, file descriptors, etc.

Discussion: What needs to be saved and restored on a context switch?

- Volatile state
  - Program counter (Program Counter (PC) also called Instruction Pointer (Intel: EIP))
  - Processor status register
  - Other register contents
  - User and kernel stack pointers
  - A pointer to the address space in which the process runs
    - the process's page table directory

…and how?

- **Save**(volatile machine state, current process);
- **Load**(another process's saved volatile state);
- **Start**(new process);

Threads and Processes
